Halo Infinite: Proof-Carrying Data from Additive Polynomial Commitments

Dan Boneh¹ Justin Drake² Ben Fisch¹ Ariel Gabizon³

¹Stanford University ²Ethereum Foundation ³AZTEC Protocol

Abstract

Polynomial commitment schemes (PCS) have recently been in the spotlight for their key role in building SNARKs. A PCS provides the ability to commit to a polynomial over a finite field and prove its evaluation at points. A *succinct* PCS has commitment and evaluation proof size sublinear in the degree of the polynomial. An *efficient* PCS has sublinear proof verification. Any efficient and succinct PCS can be used to construct a SNARK with similar security and efficiency characteristics (in the random oracle model).

Proof-carrying data (PCD) enables a set of parties to carry out an indefinitely long distributed computation where every step along the way is accompanied by a proof of correctness. It generalizes *incrementally verifiable computation* and can even be used to construct SNARKs. Until recently, however, the only known method for constructing PCD required expensive SNARK recursion. A system called *Halo* first demonstrated a new methodology for building PCD without SNARKs, exploiting an aggregation property of the *Bulletproofs* inner-product argument. The construction was *heuristic* because it makes non-black-box use of a concrete instantiation of the Fiat-Shamir transform. We expand upon this methodology to show that PCD can be (heuristically) built from any homomorphic polynomial commitment scheme (PCS), even if the PCS evaluation proofs are neither succinct nor efficient. In fact, the Halo methodology extends to any PCS that has an even more general property, namely the ability to aggregate linear combinations of commitments into a new succinct commitment that!

Abstract

Proof-carrying data (PCD) is a powerful cryptographic primitive that enables mutually distrustful parties to perform distributed computations that run indefinitely. Known approaches to construct PCD are based on succinct non-interactive arguments of knowledge (SNARKs) that have a succinct verifier or a succinct accumulation scheme.

In this paper we show how to obtain PCD without relying on SNARKs. We construct a PCD scheme given any non-interactive argument of knowledge (e.g., with linear-size arguments) that has a *split accumulation scheme*, which is a weak form of accumulation that we introduce.

Moreover, we construct a transparent non-interactive argument of knowledge for R1CS whose split accumulation is verifiable via a (small) *constant number of group and field operations*. Our construction is proved secure in the random oracle model based on the hardness of discrete logarithms, and it leads, via the random oracle heuristic and our result above, to concrete efficiency improvements for PCD.

Along the way, we construct a split accumulation scheme for Hadamard products under Pedersen commitments and for a simple polynomial commitment scheme based on Pedersen commitments.

Abstract. We introduce a new approach to realize incrementally verifiable computation (IVC), in which the prover recursively proves the correct execution of incremental computations of the form $y = F^{(\ell)}(x)$, where F is a (potentially non-deterministic) computation, x is the input, y is the output, and $\ell > 0$. Unlike prior approaches to realize IVC, our approach avoids succinct non-interactive arguments of knowledge (SNARKs) entirely and arguments of knowledge in general. Instead, we introduce and employ *folding schemes*, a weaker, simpler, and more efficiently-realizable primitive, which reduces the task of checking two instances in some relation to the task of checking a single instance. We construct a folding scheme for a characterization of NP and show that it implies an IVC scheme with improved efficiency characteristics: (1) the “recursion overhead” (i.e., the number of steps that the prover proves in addition to proving the execution of F) is a constant and it is dominated by two group scalar multiplications expressed as a circuit (this is the smallest recursion overhead in the literature), and (2) the prover’s work at each step is dominated by two multiexponentiations of size $O(|F|)$, providing

Along the way, we construct a split accumulation scheme for Hadamard products under Pedersen commitments and for a simple polynomial commitment scheme based on Pedersen commitments.

Abstract.

This paper introduces *HyperNova*, a recursive argument for proving computational computations whose steps are expressed with CCS (Setty et al. 2023), a customizable constraint system that simultaneously generalizes R1CS, and AIR without overheads. A distinguishing aspect of HyperNova is that the prover's cost at each step is dominated by a *single* multiplication (MSM) of size equal to the number of variables in the constraint system, which is optimal when using an MSM-based commitment scheme.

To construct HyperNova, we generalize folding schemes (CRYPTO 2023) to allow instances from two (potentially) different NP relations, that share the same structure, to be folded; we refer to this generalization as *multi-folding*.

REDUCE - AND - COMBINE

HyperNova [KS23]

REDUCE - AND - COMBINE

HyperNova [KS23] - a small detour via CCS and SuperSpartan [STW23]

$$Az \circ Bz - Cz = 0$$

The diagram shows a mathematical equation involving three matrices: Az , Bz , and Cz . The equation is $Az \circ Bz - Cz = 0$. The matrices are represented by grids of colored squares. Az is a 4x4 grid of light blue squares. Bz is a 2x2 grid of white squares. Cz is a 4x4 grid of light purple squares. The operation \circ between Az and Bz indicates a Hadamard product (element-wise multiplication). The result of this product is then subtracted from Cz . The final result is a 2x2 grid of white squares, representing the zero vector $\vec{0}$.

HyperNova [KS23] - a small detour via CCS and SuperSpartan [STW23]

$$Az \circ Bz - Cz = 0$$

The diagram shows a mathematical expression involving matrices and vectors. On the left, there is a 4x4 matrix with light blue cells. To its right is a vertical vector with four light blue cells. An operation symbol (\circ) is placed between the matrix and the vector. To the right of the vector is another operation symbol ($-$). Following the minus sign is a 4x4 matrix with light purple cells. To its right is a vertical vector with four light purple cells. The entire expression is followed by an equals sign and a horizontal arrow pointing right ($\vec{0}$), indicating that the sum of the two terms is the zero vector.

Spartan [Set20] is a two-layered sumcheck based proof for R1CS

HyperNova [KS23] - a small detour via CCS and SuperSpartan [STW23]

$$Az \circ Bz - Cz = 0$$

The diagram illustrates the equation $Az \circ Bz - Cz = 0$. It shows three components: a 4x4 grid of light blue squares representing matrix A , a vertical column of four light blue squares representing vector z , and a 4x4 grid of light blue squares representing matrix B . An operation symbol \circ is placed between the first two components, indicating element-wise multiplication. A minus sign $-$ is placed before the third component, which is a 4x4 grid of light purple squares representing matrix C . The result of the entire expression is a vertical column of four white squares, representing the zero vector $\vec{0}$.

Spartan [Set20] is a two-layered sumcheck based proof for R1CS

Sumcheck 1 (zero check):

$$a \circ b - c = 0$$

The diagram illustrates the sumcheck 1 (zero check) for the equation $a \circ b - c = 0$. It shows three components: a vertical column of four light blue squares representing vector a , a vertical column of four light blue squares representing vector b , and a vertical column of four light purple squares representing vector c . An operation symbol \circ is placed between the first two components, indicating element-wise multiplication. A minus sign $-$ is placed before the third component. The result of the entire expression is a vertical column of four white squares, representing the zero vector $\vec{0}$.

HyperNova [KS23] - a small detour via CCS and SuperSpartan [STW23]

$$Az \circ Bz - Cz = 0$$

A diagram illustrating a linear combination of matrix-vector products. It shows three terms: a light blue square matrix multiplied by a white vector, followed by a dot product symbol (\circ), another light blue square matrix multiplied by a white vector, followed by a minus sign ($-$), and finally a purple square matrix multiplied by a white vector. The result is set equal to a zero vector ($\vec{0}$).

Spartan [Set20] is a two-layered sumcheck based proof for R1CS

Sumcheck 1 (zero check):

$$a \circ b - c = 0$$

A diagram illustrating a linear combination of vector products. It shows two terms: a light blue vector multiplied by a light blue vector, followed by a dot product symbol (\circ), and then a minus sign ($-$), followed by a purple vector multiplied by a white vector. The result is set equal to a zero vector ($\vec{0}$).

Sumcheck(s) 2 (“linchecks”, i.e. matrix-vector products):

$$Az = a, Bz = b, Cz = c$$

A diagram illustrating matrix-vector multiplication. It shows three terms: a light blue square matrix multiplied by a white vector, followed by an equals sign ($=$), another light blue square matrix multiplied by a white vector, followed by an equals sign ($=$), and finally a purple square matrix multiplied by a white vector, followed by an equals sign ($=$).

Sumcheck 1 (zero check):

$$m_1 \circ m_2 \circ m_2 + m_3 + m_4 \circ m_2 - 3 m_3 \circ m_5 = 0$$

$$\begin{matrix} \text{cyan} \\ | \\ | \\ | \\ | \\ \end{matrix} \circ \begin{matrix} \text{cyan} \\ | \\ | \\ | \\ | \\ \end{matrix} \circ \begin{matrix} \text{cyan} \\ | \\ | \\ | \\ | \\ \end{matrix} + \begin{matrix} \text{orange} \\ | \\ | \\ | \\ | \\ \end{matrix} + \begin{matrix} \text{white} \\ | \\ | \\ | \\ | \\ \end{matrix} - 3 \begin{matrix} \text{orange} \\ | \\ | \\ | \\ | \\ \end{matrix} \circ \begin{matrix} \text{orange} \\ | \\ | \\ | \\ | \\ \end{matrix} = \vec{0}$$

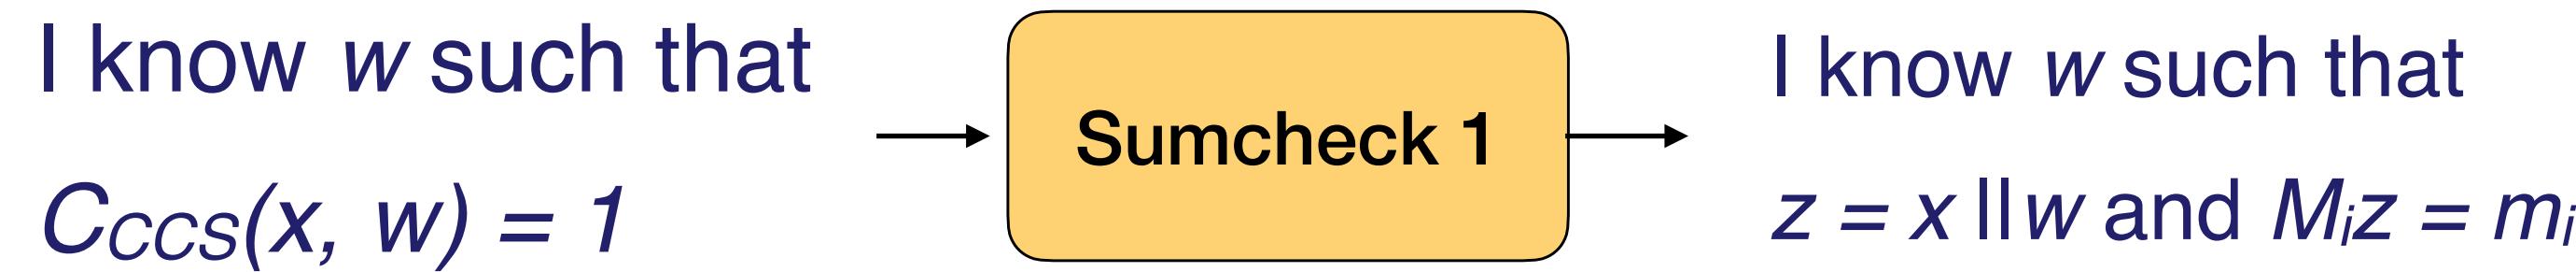

Sumcheck(s) 2 (“linchecks”, i.e. matrix-vector products):

$$M_iZ = m_i$$

$$\begin{matrix} \text{cyan} & | & \text{white} \\ | & | & | \\ | & | & | \\ | & | & | \\ \end{matrix} = \begin{matrix} \text{cyan} \\ | \\ | \\ | \\ | \\ \end{matrix}$$
$$\begin{matrix} \text{orange} & | & \text{white} \\ | & | & | \\ | & | & | \\ | & | & | \\ \end{matrix} = \begin{matrix} \text{orange} \\ | \\ | \\ | \\ | \\ \end{matrix}$$
$$\begin{matrix} \text{purple} & | & \text{white} \\ | & | & | \\ | & | & | \\ | & | & | \\ \end{matrix} = \begin{matrix} \text{purple} \\ | \\ | \\ | \\ | \\ \end{matrix}$$

HyperNova [KS23]

HyperNova [KS23]

I know w such that
 $C_{CCS}(x, w) = 1$

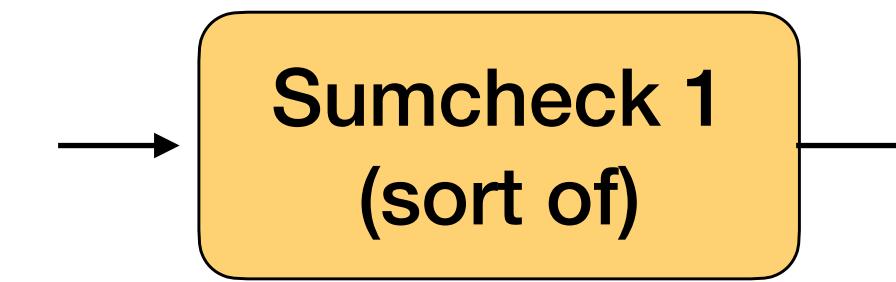

I know w such that
 $z = x \parallel w$ and $M_i z = m_i$

This is linearised CCS! (almost)

HyperNova [KS23]

I know w such that
 $C_{CCS}(x, w) = 1$

I know w such that
 $z = x \parallel w$ and $M_i z = m_i$

This is linearised CCS! (almost)

HyperNova [KS23]

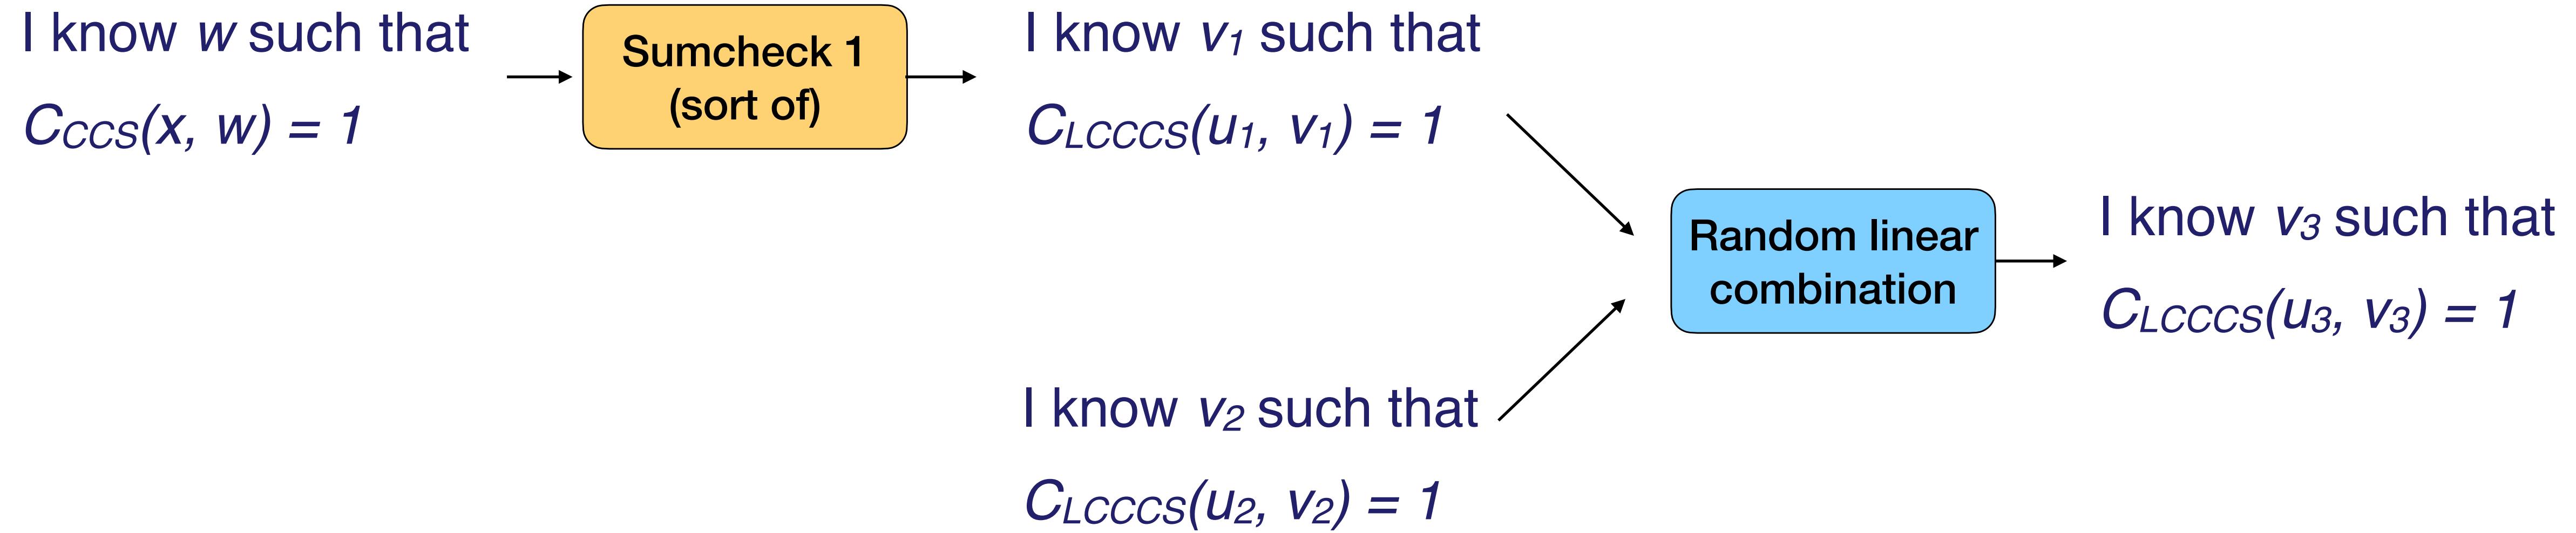

I know w such that
 $C_{CCCS}(x, w) = 1$

→ Sumcheck 1
(sort of)

→ I know v_1 such that
 $C_{LCCCS}(u_1, v_1) = 1$

HyperNova [KS23]

ProtoStar [BC23]

I know w such that

$$f(x, w) = 0$$

ProtoStar [BC23]

I know w such that
 $f(x, w) = 0$

I know w , all the messages m_i and challenges r_i such that:
 $C_i = \text{Comm}(m_i)$
 $\text{relaxed_verif}(x, m_i, r_i, \mu) = e$

ProtoStar [BC23]

I know w such that
 $f(x, w) = 0$

I know w , all the messages m_i and challenges r_i such that:
 $C_i = \text{Comm}(m_i)$
 $\text{relaxed_verif}(x, m_i, r_i, \mu) = e$

I know w , all the messages m_i and challenges r_i such that:
 $C_i = \text{Comm}(m_i)$
 $\text{relaxed_verif}(x, m_i, r_i, \mu) = e$

I know w , all the messages m_i and challenges r_i such that:
 $C_i = \text{Comm}(m_i)$
 $\text{relaxed_verif}(x, m_i, r_i, \mu) = e$

Comparing the latest schemes

Protocol	\mathcal{R}	\mathcal{S}	“Reduce” work	“Combine” work
Nova	R1CS	committed relaxed R1CS	P: commit to the witness V: none	P: commit to the error term V: add commitments with 1 error term
HyperNova	CCS	linearised committed CCS	P: commits to the witness, then P and V run the sumcheck protocol	P: random linear combination V: random linear combination
ProtoStar	any relation with algebraic verifier	commitments to all the messages and compressed verifier check	P: commit to each message V: produce random challenges	P: compute the compressed cross terms V: add commitments and compressed cross terms

Conclusion

- My mental model for folding schemes: **reduce-and-combine**
- Seems there is a trade-off between how much work we do in reduction and how easy it is to fold the resulting relation
- Language suggestion: let's say folding for all protocol in this class, easier on the ear than split accumulation or multi-folding
